Feedback from Judges
Judges 1
Rigorous and well-connected method with results flow consistently into fuel, CO2 and economic outcomes that can be traced and re-calculated. The team's honesty in reporting that full reliability equivalence was not reached, and in naming the parameters that drive the result, adds real credibility. Future improvement includes: proofread for small inconsistencies such as the different ERA5 coordinates in Section 2.3.2 and Appendix C, the "2,05 kW" entry in Table F1 and the repeated or skipped section numbers; show what standby-generator start reliability would be needed to fully match the N+1 baseline; and discuss battery degradation, replacement and offshore fire-safety requirements, which affect both feasibility and cost.
Judges 2
Idea paper in accordance with energy transition, the 4th turbine as backup replaced by battery, the result saves fuel and lowers CO2 emissions, maybe the paper title needs to be updated, its LOLP rises from 0.89% to 0.96% which seems not equivalent,. Its improvement needs further discussion regarding usage safety and battery durability offshore and its comparative analysis with other non-battery solutions. Final BESS 2.05 MW thin margin with failure limit 2 MW,
Judges 3
Concept already exist in a real platform based on Jacob, et.al. 2018 (reference). Authors emphasized strongly on reliability calculation (temperature based analysis) which did not provide in previous publication. Inovation is not new in offshore platform. This paper can be more useful if author consider additional energy source, e.g. wind or solar energies. The team's calculations are accurate and consistent: every main result, from reliability and battery size to fuel, CO_2, NPV and payback, reproduces exactly when rechecked The paper covers the problem from several angles in one framework: reliability, temperature-dependent engine performance, fuel and CO_2 savings, and economics. Its strongest link to the theme is efficiency. Finally, the topic is practical and grounded in real industry practice, as shown by Woodside's Goodwyn A platform.

Feedback from Judges
Judges 1
The main area for improvement is consistency. The abstract and conclusion report economics based on a US$60/t storage incentive while the results section uses the blue-ammonia premium, so the NPV, IRR, payback, supplier cost and urea threshold differ, and Appendix D follows the incentive basis; the final version should present one design case consistently or clearly show both. Need to address how realistic it is for the supplier to cut about 28% of its urea output.
Judges 2
An interesting paper aligned with the theme, there are several inconsistencies, the base case economic option figures in the paper and poster are different (whether receiving incentives or not), EOR reserve estimation should use reservoir simulation instead of analytical correlation. Large CAPEX makes economics sensitive to small changes in reserves, oil price, and blue ammonia premium price. the requirement for Gross Split limit at 78% is too high, first injection in 2027 is too optimistic
Judges 3
1. significant differences on NPV between full text and poster, this likely authors put diferrent values and makes the NPV differ significantly. 2. simple calculation honor reservoir engineering principle, even though dynamic simulation is desirable. This is matter because estimated recovery of 3.10 MMSTB is approximately 19.6% higher than the 2.59 MMSTB compositional simulation benchmark referenced in the paper 3. plus point emphasizing net CO_2 removed.

Feedback from Judges
Judges 1
It builds a true cascade at an existing geothermal site, where brine heat powers an ORC, the electricity drives AEM electrolysis, the electrolyzer's waste heat is upgraded for membrane distillation, and the oxygen by-product is reused for H2S abatement. The ORC model is validated against published data. To strengthen the work, there should be an additional analysisi regarding techno-economic assessment (CAPEX, LCOH, value of water and oxygen) and compare the scheme with simply exporting the ORC power; and explain how membrane distillation would operate above 100 C and how the reinjection SSI of 1.45 will be managed, given the 1-1.2 target cited.
Judges 2
This study presents innovative and optimistic concept, but still relies entirely on theorical data without field experimental validation, the lack of economical analysis and high possiblity of operational risks limit real application of this paper
Judges 3
The concept is interesting, and some of the calculations are consistent. However, they still need to demonstrate that the system will not cause issues for the reinjection wells, that the chosen process is truly optimal, and that the additional facility costs are economically viable.

Feedback from Judges
Judges 1
Great technical depth and originality. Each sub-model is validated, uncertainty is acknowledged openly, and the economic conclusion is honest and decision-useful, stating clearly which phase is viable and under what injection cost. Main text should stand on its own, as much of the evidence now sits in a 26-page appendix, key figures and tables should be brought into the body and only supporting detail kept in the appendix.
Judges 2
EOR ratio need to validated with resevoir simulation, need further analysis for injection and storage cost that can make the project uneconomic
Judges 3
1. The assumption for incremental oil (bbl/ton of CO2 injected) appears overly crude and static. A dynamic simulation or an analytical model is required to provide a realistic figure consistent with reservoir engineering principles. This is crucial, as it significantly impacts the overall economics presented by the authors. 2. The assumptions regarding Minimum Miscibility Pressure (MMP) and well hydraulics effectively imply 100% efficiency for CO2 entering the reservoir and achieving miscibility with the oil. 3. Overall, the paper is well-constructed, employing an integrated engineering approach, and it acknowledges certain limitations (e.g., uncertainty regarding MMP). However, it lacks sufficient emphasis on the net carbon reduction achieved.

Feedback from Judges
Judges 1
Consistency is needed for figure between the abstract, tables, text, figures and posters as the annual savings, model R2, MR flow rates, minimum temperature approach and optimized SEC are reported differently in different places. Need to xplain why compressor power falls by about 27% while turbine steam falls by only about 6.5%, which is unexpected for steam-driven compressors, and validate this against plant data.
Judges 2
combining smart machine learning with real plant data.However, many numbers do not match across the abstract, tables, and the savings come from a simulation rather than real plant trials. Fixing these inconsistencies, confirming the simulation matches plant data, and proofreading carefully would make the paper much better
Judges 3
A cheap idea, changing the refrigerant recipe needs almost no new equipment. Theme fit: optimization, efficiency and lower CO_2.

Judges 3
a creative, well-organized plan to turn Dieng's waste hot brine into clean heat and four products,Its calculations are consistent, but the plan is still untested. Key assumptions, such as , product purity and market, and the high lithium price, are unproven, and the profit estimate depends on cost savings and excludes taxes. Fix the few inconsistencies, then validate it in the lab and a pilot
Judges 3
The design solves Dieng's real silica problem in a smart way, and the team is honest about what is unproven. The paper fits the theme very well.

Feedback from Judges
Judges 1
Judges 2
The idea is relevant and well organized, and the authors are honest that it is only a first test. But the results come from made-up data and guessed costs, so it is not yet proven that the system really works.The poster should say clearly that the numbers are simulated. several factors need to further evaluated beside history data
Judges 3
1. the paper addresses production (flare gas) as well as environmental challenges by proposing integrated framework for flare gas forecasting, and reducing flared gas for own used. 2. Authors acknowledge the limitation of the dataset (syntetic data) and used old historical data set from 2014. 3. good concept but based on my personal view, mechine learning in this case is redundant comparing with conventional control. For instance, gas flared can be just forecast using historical oil rate and GOR. 4. The poster presents forecasting without stating that the data generated were syntetic
